# Problem Description

- Current American politics is very divided along party lines
- We want to see if this political divide shows up in the data
- Can members of congress be clustered into the two parties based on their voting record?
  - Do members of the same party tend to vote with each other?
  - Are some members willing to vote against their own party?
  - Are there some members that are hard to classify based on their voting recording?

# Data Mining: Web Scraping

Web Scraping: collected relevant data from a given website

- For every bill, take the congressperson and their vote on said bill
- Collect this information on all bills to build a data set

We haven't done this in class, so let's take a look at what this looks like!

# Voting Records

TRACK VOTES

Get an email every time Congress votes on a bill or other matter.

Each year the U.S. Senate and House of Representatives take thousands of votes, some to pass bills, resolutions, nominations, and treaties, and others on procedural matters such as on cloture and other motions. Not all votes are recorded, such as when there is no one opposed. This page shows the outcome of all recorded votes on the Senate floor and House floor. It does not include votes in committee.

# Data Cleaning

Problem	Solution
Two word states listed in multiple indices (list[0] = "New", list[1] = "York")	Append indices together where this happened
Not every member of congress votes on every bill, ragged data set	Create a list of all congress people, add missing people into bills they didn't vote on. <u>Assume they would vote with their party.</u>
Data in string format "Yea" or "Nay"	Encode string values "Nay" = 0, "Yea" = 1

# Clean Data

	Name	State	Party	Bill_1	Bill_2	Bill_3	Bill_4	Bill_5	Bill_6	Bill_7
0	a_dutch_ruppersberger	Maryland	Democrat	1	1	1	1	0	1	1
1	abigail_spanberger	Virginia	Democrat	1	1	1	1	0	1	1
2	adam_kinzinger	Illinois	Republican	1	0	0	0	1	0	1

# Data Analysis

Finding the mean count of democrats and republicans who voted against their party for all 311 bills

Gives us an idea about voting behaviour and certain outliers

```
# On average, 3 democrats voted against their party  
np.mean(demAgainst)
```

```
3.867741935483871
```

```
# On average, 12 republicans voted against their own party  
np.mean(repAgainst)
```

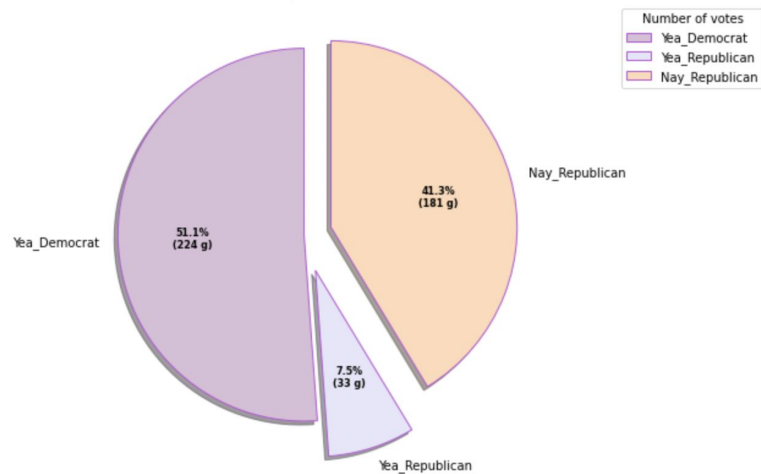

```
12.993548387096775
```

# Data Visualization

```
# LGBTQ Business Equal Credit Enforcement and Investment Act  
df.groupby("Bill_180")["Party"].value_counts()
```

```
Bill_180  Party  
Nay       Republican    181  
Yea       Democrat     224  
          Republican     33  
Name: Party, dtype: int64
```

H.R. 1443: LGBTQ Business Equal Credit Enforcement and Investment Act

H.R. 7: Paycheck Fairness Act

H.R. 3755: Women's Health Protection Act of 2021

# Model Creation

- We want some algorithm that can look at how each person voted and classify them
- First need to define some distance metric to determine how close one congressperson is to another — many such metrics exist: Manhattan, Euclidean, Cosine Similarity, Jaccard, and more
- Use an algorithm that can take in the distances to make clusters
  - Will everyone cluster into their own party?
  - Will there be some people who are difficult to cluster?

## Jaccard Distance

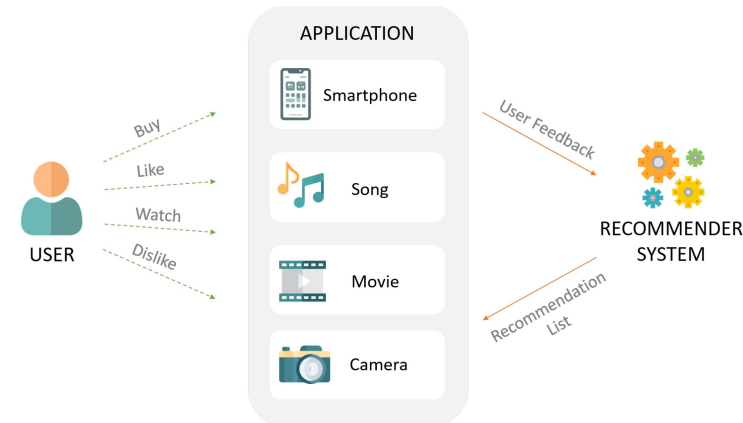

$$J(A, B) = \frac{|A \cap B|}{|A \cup B|}$$

- Generally speaking, the Jaccard index is used when there are binary situations. This is fitting in our context as we manipulated the data to go from 3 voting options (Yea, Nay, Not Voting) to 2 options (Yea, Nay) with data imputation — based on mode of data set since such small percentage voted against their party.
- Aided in binarizing the choices.

# Jaccard Distance Use Cases

- Recommendation Systems
- E-Commerce
- In Natural language processing, Jaccard distance is often used to measure text similarity analysis — how much word choice overlap exists between documents. This pattern analysis is often used for plagiarism detection.

# Jaccard Distance Results

abigail\_spanberger adam\_kinzinger

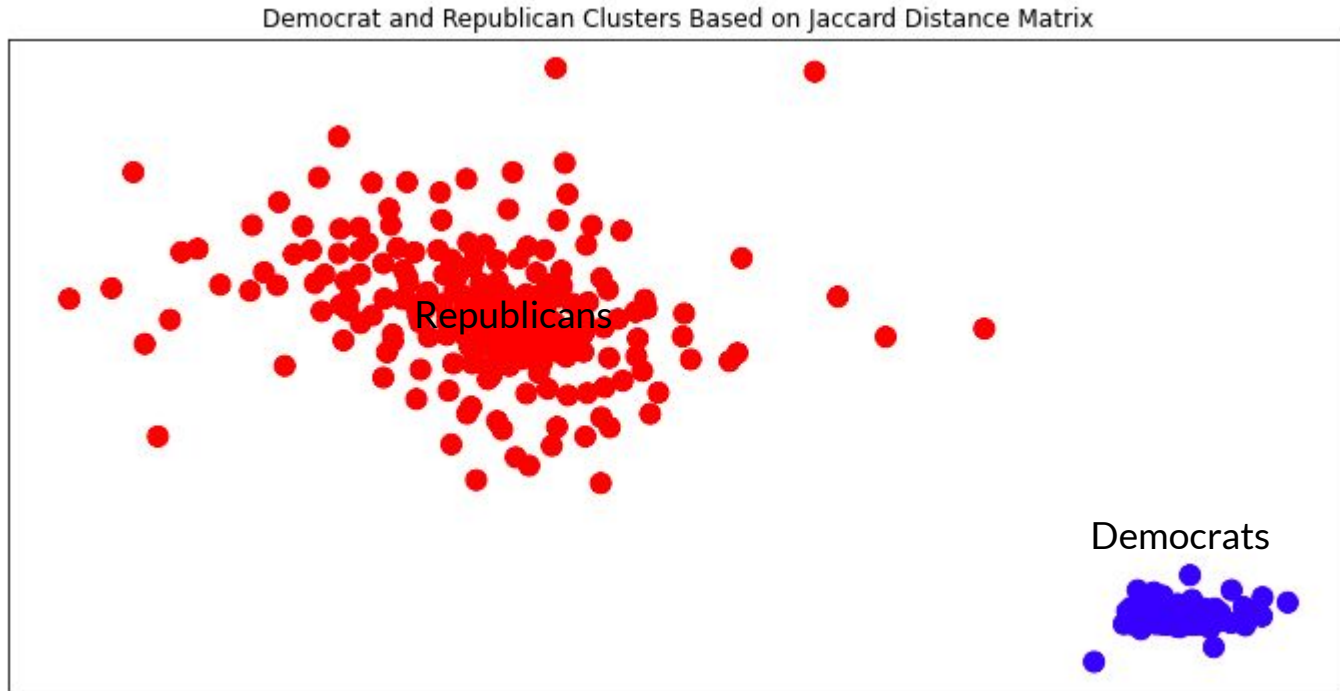

1	1
1	0
1	0
1	0
0	1
1	0
1	1
0	0
0	0
1	0

- Often used to measure similarity and diversity of data sets.
- Jaccard Distance = intersection of A&B/Union of A&B
  - Elements of A in B/All elements in A and B
- Where both people vote together/All votes
- $J(\text{Spanberger}, \text{Kinzinger}) = 0.61$ . This is a relatively high distance between politicians, suggesting perhaps they are polar and that they disagree on most issues.
- We can then produce a distance matrix- distance from one person to everyone else

```
[0.      , 0.0444, 0.6327, 0.0242, 0.0283]
[0.0444, 0.      , 0.6103, 0.0593, 0.0558]
[0.6327, 0.6103, 0.      , 0.64   , 0.6409]
[0.0242, 0.0593, 0.64   , 0.      , 0.0121]
[0.0283, 0.0558, 0.6409, 0.0121, 0.      ]
```

# Plotted Distance Matrix

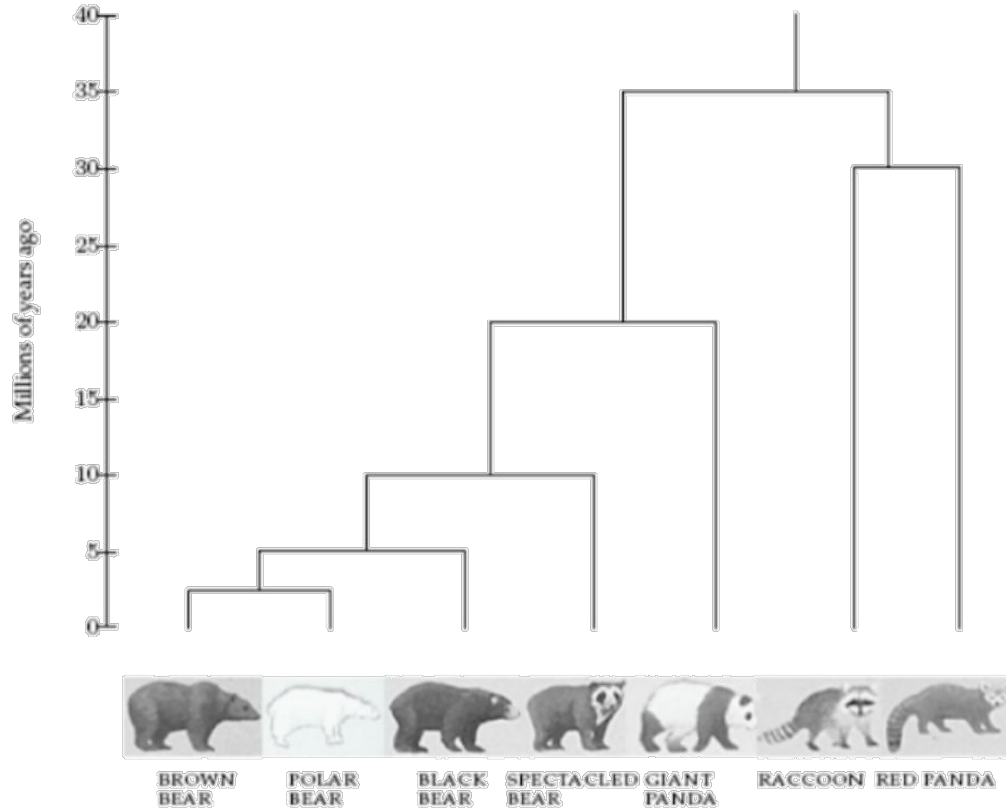

# Hierarchical Clustering

- Given the distances between each point we can use Hierarchical Clustering
- This will group all points closest to each other then group all clusters closest to each other

# Hierarchical Clustering Example

# Results

## Accuracy

$$(Y_{\text{pred}} == Y) / \text{len}(Y) * 100$$

$$= 100\%$$

# Conclusion

- Initial analysis in the data reflected the political division in congress
- This was further shown by using a distance metric to measure see how close/far people voted in their own party
- The vast difference in voting between the parties made clustering them accurately easy
